

Business Case for EKG

Reframing the Problem

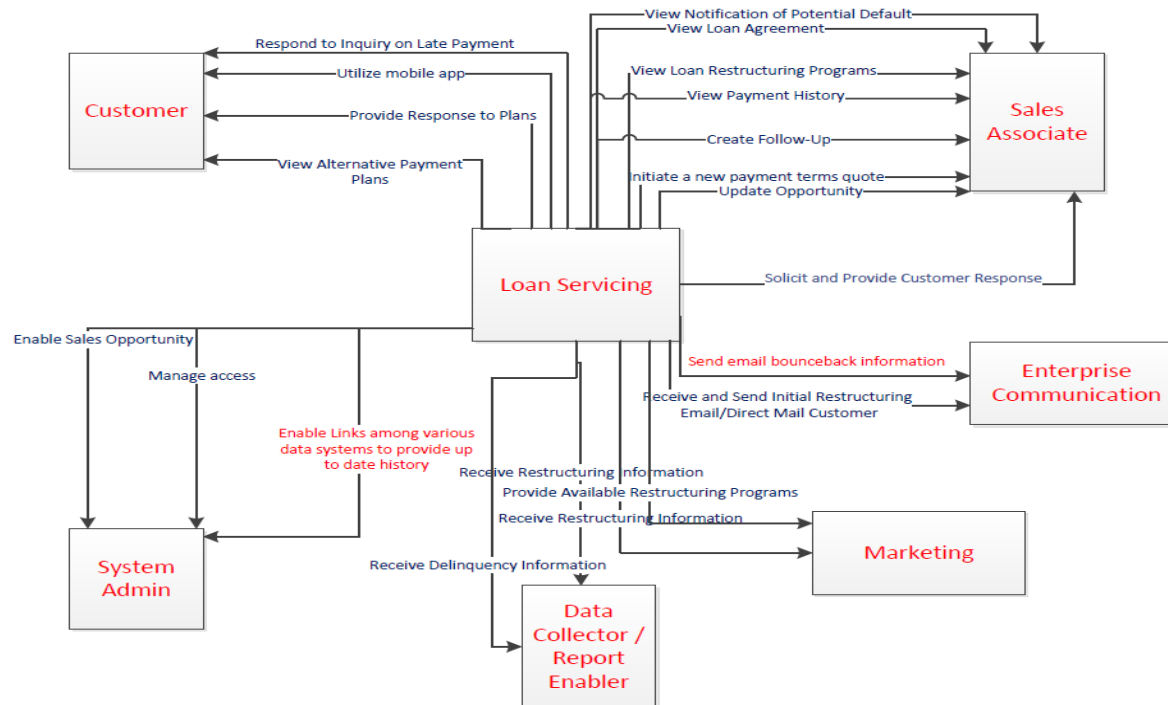

Assertion:

We need to stop referencing organizations and their value chains using simple enterprise modeling paradigms. The distributed nature and accelerating pace of change requires a different approach.

Recommendation:

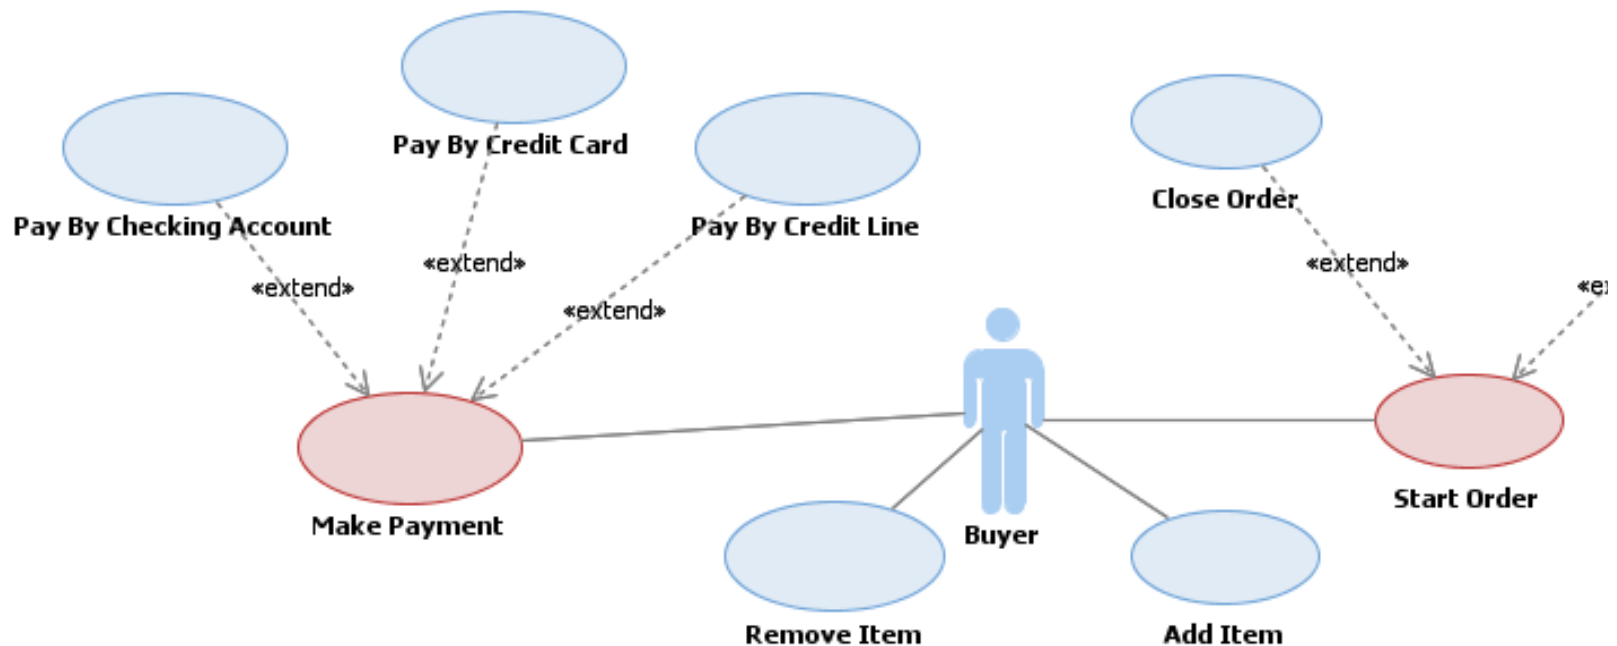

Reframe the "enterprise" as a complex adaptive system since there is no way to fully understand all aspects of change and impact.

Relationship Map for 1 Process

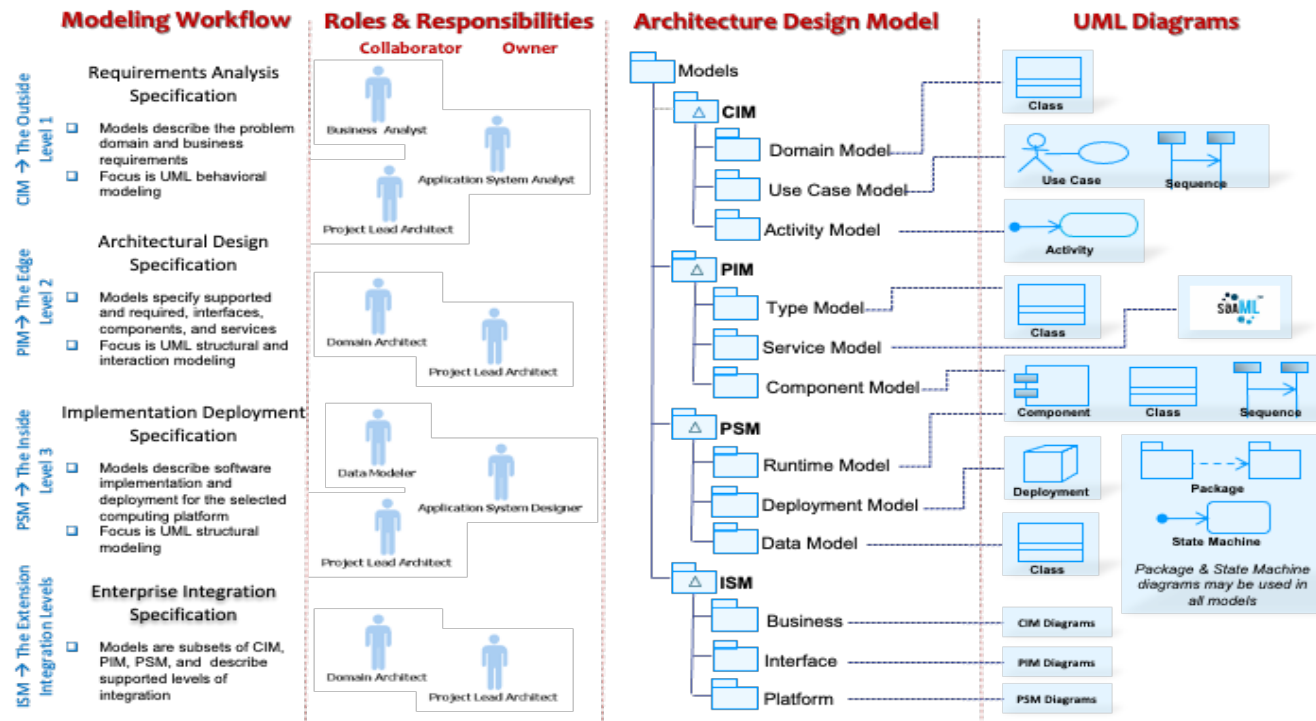

This is just ONE process example and the full extent of these relationships is not well understood. These are simplistic abstractions for an activity, where each one will reveal multiple desired outcomes for the stakeholders.

Use Case for CC Payment

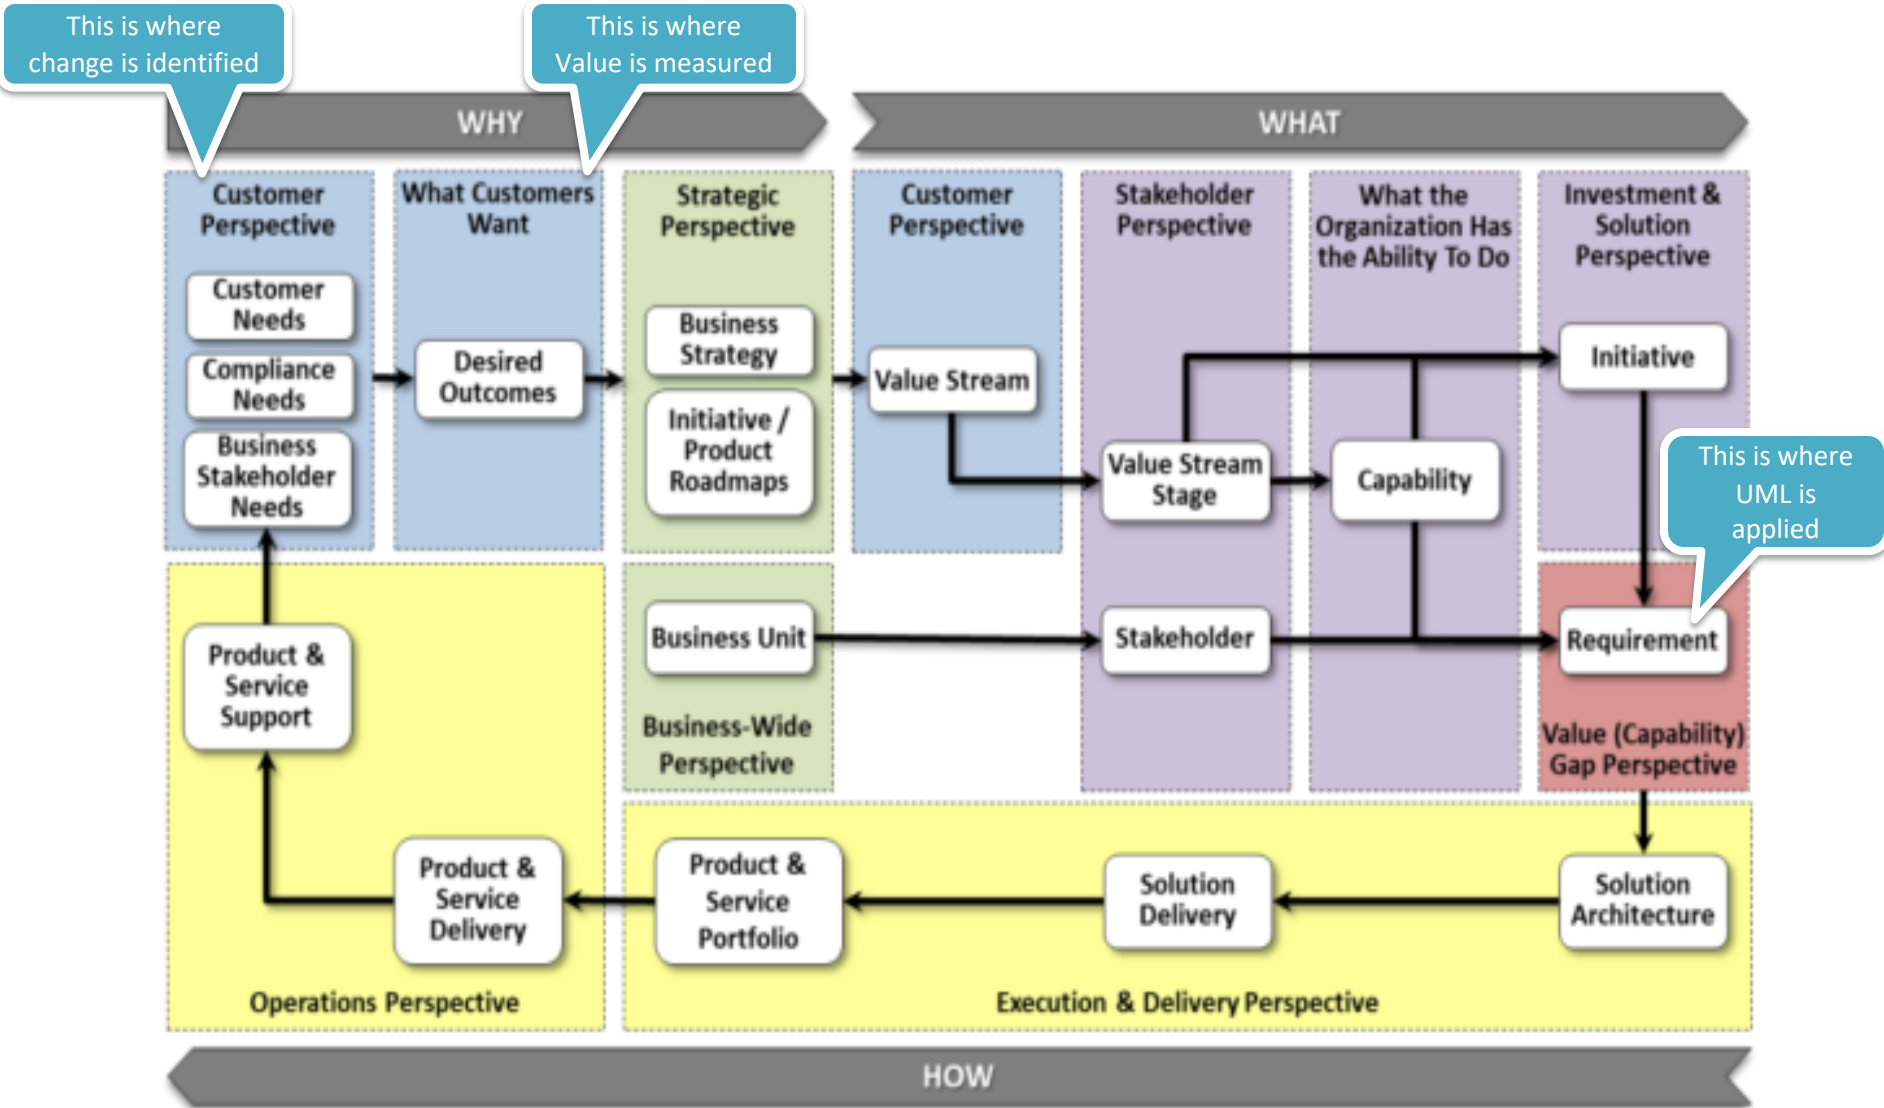

This is a simplistic rendering of process activity, roles, and actors for capturing the bare minimum understanding to engineer a functional solution for a business scenario.

Mapping Across Models

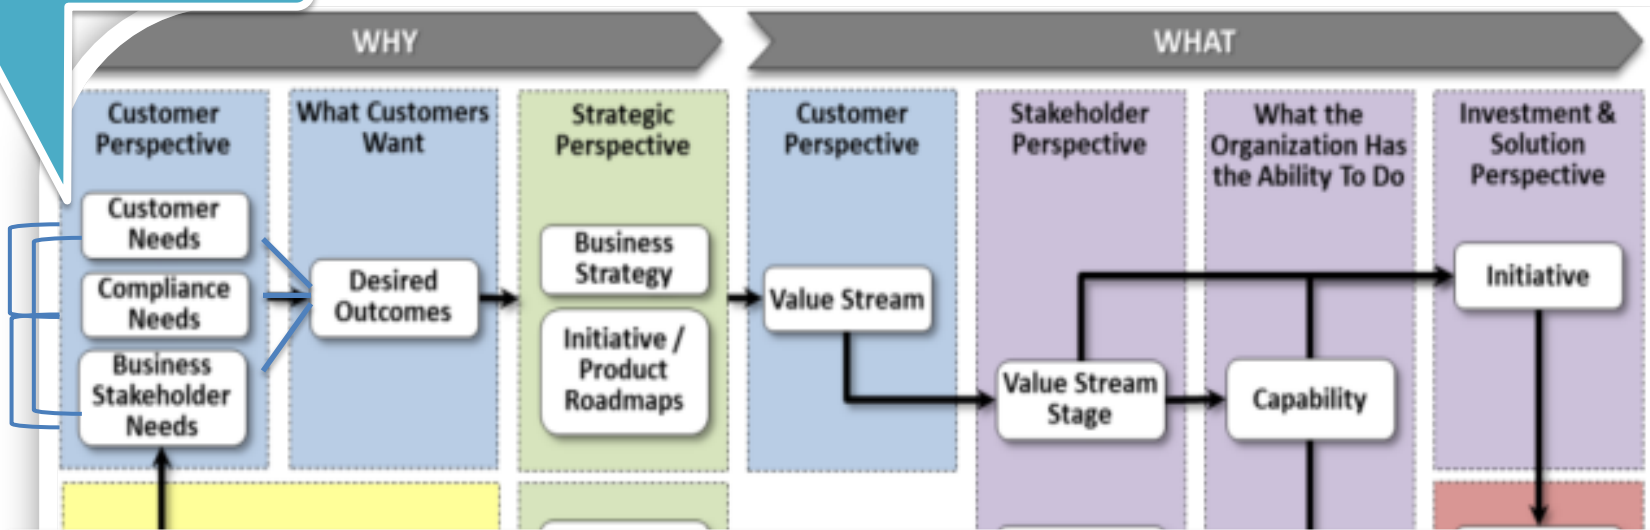

This is a simplistic rendering of process activity, roles, and actors for capturing the bare minimum understanding to engineer a functional solution for a business scenario.

Mapping change across perspectives of understanding using a conventional mapping paradigm is proving untenable to maintain let alone understand.

Reference Model: Alex Randell, Eric Spellman, William Ulrich, Jeffrey Walk. "Leveraging Business Architecture to Improve Business Requirements Analysis – A Business Architecture Guild White Paper," Mar. 2014.

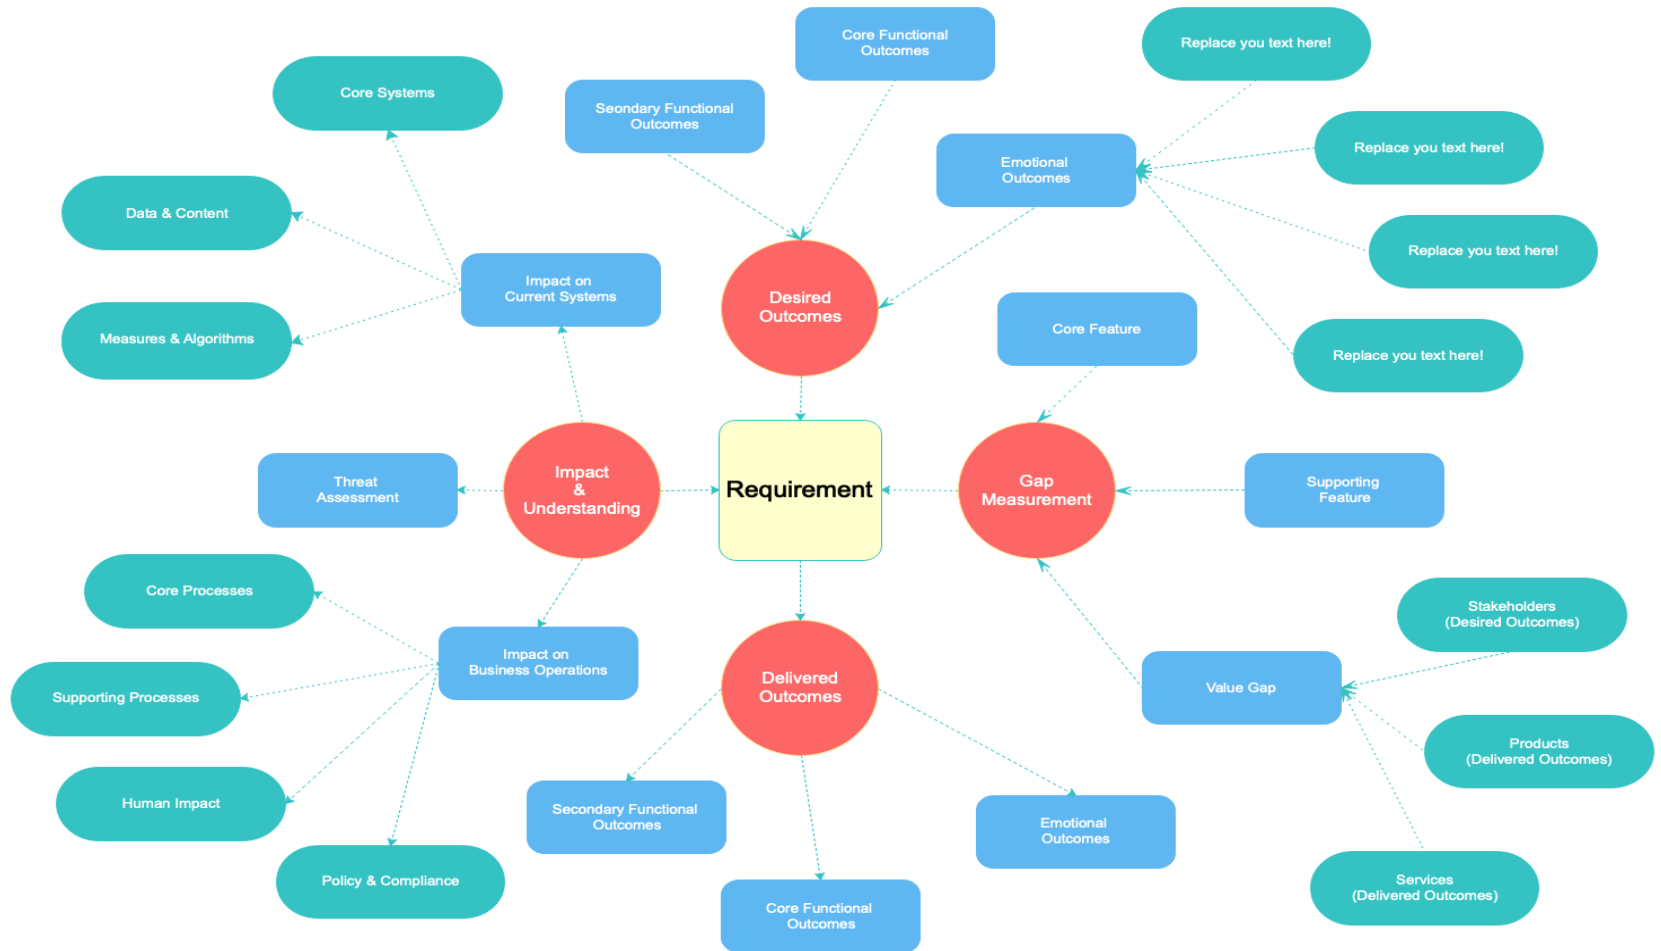

Small sample of the mapping complexity (Level 1 Only)

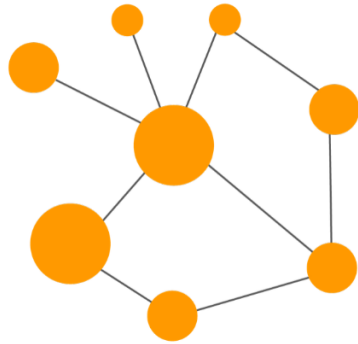

This is just a tiny fraction of the relationships that need to be captured throughout the change lifecycle for an organization.

Each arrow represents a M:M cardinality across multiple levels.

Conventional approaches using hierarchical decomposition do not work and cannot scale the current needs for defining cause and effect (known) and does not support inferred causal factor analysis patterns from ML to anticipate (predict) impact when change happens.

The use of knowledge graphs is the **ONLY** efficient and scalable solution for capturing and managing multi-dimensional relationships across domains in a complex adaptive system (data, assets, concepts, value, and change across organizations and value chains)
