Issue Management

Change is Complex

Issue Management

5-Step Process to “Feed the Pipeline”

Ideally, everything would just “flow” through the pipeline. Many organizations can make good use of this simplified approach.

But they may not be solving the RIGHT problems.

They also tend to struggle with innovation.

Simple View of Change & Issue Management

Definition & Context

- Issue - Anything occurring outside of normal current state operations that can impact the organization and/or its stakeholders.
- The source for that issue can be any type of CHANGE that can occur within an organizations and/or outside of an organization.
- Change happens at an accelerating pace, so formalizing the capture and management of issues is becoming a must-have capability.

Types of Issues

Issue – anomalies which occur in production (products/services)

- Severity is a further classification which identifies impact to the organization, systems, and its customers
- Incidents are a further classification which occur when a customer is impacted. Note: if a customer / patient is injured or death occurs, these incidents become reportable to one or more regulatory authorities

Defects – concerns / anomalies which occur in across the lifecycle development (products or software)

- These need to be tracked with problems since some (many) of these defects may not be addressed during lifecycle development but remain “dormant” as potential risk

Requests – internal / external requests for change

- Customers / patients requesting changes in products / services may be an indicator of either problems or defects. Typically, these are missed requirements or opportunities that were never discovered during conceptualization
- Internal staff may identify opportunities for improvement (using formal methods like LEAN, 6Sigma, or Kaizen) or informally through experience and simple observation

Change is Complex

Sense

Diagnose

Innovate

Change is Complex

Sense Change

- Change Happens, so we monitor sources and develop sensors to detect change
- When Changes is identified, we capture them as issues
- Assess impact of of each issue
- Prioritize the issues
 - If issues are urgent, they are Triaged
 - If issues are not urgent, they are diagnosed

Change is Complex

Diagnose Issues

- Diagnose Issues (symptoms?) so we can figure out the right problem to solve
 - Identify Causal Factors (CFs)
 - Document the Problem – one or more CFs
 - Map Problems to other Problems (related?)
 - Map Problems to other Issues

Change is Complex

Innovate

- Generate ideas and/or map ideas from the existing repository to solve the problem
- A solution is mapped to one or more initiatives
- Initiatives are prioritized and catalogued and bucketed into a project
- Projects are funded to design, build and implement the solution

Big Picture

Change is
Complex

Issue Management

Managing Complexity

Issue Management

Formalized

- Providing a centralized capability to manage issues, risks, questions, and tasks.
- Provide a baseline model to feed into Demand Management
- Provide a holistic capability for driving change and identifying opportunities across operational areas as well as transitional activities (associated with change management & acquisition management).

Benefits of Formal Issue Management

- Identify common sources of problems
- Surfaces frustrations in an objective manner
- Provides insights for addressing multiple problems
- Provides data to manage up and out
- Creates visibility around patterns that can be address proactively
- Gain insights around causality (results in recurring issues impacting multiple projects)
- Reduce the amount of time dedicated to discussing and surfacing issues
- Optimize resource utilization by replacing meeting time with dashboards & metrics
- Improve the ability to anticipate issues and perhaps reduce/eliminate their impact
- Improve our ability to focus on priorities by reducing “noise”
- Reduce the amount of churn on projects and while improving productivity
- Moves us towards an ability to identify and solve the right problem instead of focusing on every issue

Formalizing Issue Management

WHAT

WHERE

WHO, WHY, & HOW

Formalizing Issue Management

WHAT

Issues can impact any one or more products and initiatives (including operations). By raising issue management into the realm of compliance, the organization can build systematically drive continuous improvement throughout the organization (and across its supply chain partners).

Formalizing Issue Management

WHERE

Issues can occur at any point in our operations as well as service delivery for our customers. Organizations focused on moving service delivery further up the value creation (PLM) as well as value delivery (SCM), so the opportunity for tracking issues across the product lifecycle and driving continuous improvement for customers is huge.

We also want to track issues that impact our operational excellence across the various functions and Business Unit's since these can impact service delivery as well as effectiveness.

Formalizing Issue Management

WHO, WHY, & HOW

Once issues have been captured, they need to be analyzed for causal factors to identify why and how the issue arose and which resources (who) were involved. This requires disciplined techniques combined with tools for performing forensic analysis.

Managing Change & Complexity

- Issue Management is the main feed used to drive change in organizations. Issues are a superset of issues, requests, defects, associated initiated from one or more internal or external sources of change.
- Recommendations for changing current state are derived from examining issues, which are then bundled into projects or tasked out to support and/or operations staff to implement.
- The goal for continuous improvement is to reduce the likelihood of issues recurring (i.e. don't repeat mistakes) thus reducing the backlog of reactionary work. Proactive work should be the bulk of requests in the pipeline once a steady-state level of maturity is achieved.
- In order to achieve this level of maturity, all issues need to be captured and tracked using a consistent data model to conduct patterned-based mining of root causes and/or opportunities.

We will elaborate further on Demand Management in a separate presentation
